

Network File System

Michael Tsai
2025/04/28

Agenda

- 記得點名
- Lecture: Network Storage (NFS)
- Lab 9: NFS
- HW9公布

Network File Services

- Created by Sun Microsystems for diskless clients in 1984
- Goal:
 - Share filesystems among computers
 - Transparent to users
(as if the files is stored locally)
 - No information is lost when the server crashes
- Get better in the last 25 years
(very complex, bugs in unusual situations)

Related Terms

- Storage Area Network (SAN): serve blocks (not files)
 - Example: iSCSI
- Network Attached Storage (NAS):
file-level data storage attached to the network
 - v.s. Direct Attached Storage (DAS)
- Server Message Block / Common Internet File System (SMB/CIFS)
 - Microsoft Windows Network —> Active Directory
 - Samba: Implementation on Unix-like systems
- Apple Filing Protocol (AFP) -
abandoned, no longer supported since MacOS Big Sur (11.0)

Reading: Object Storage

- MINIO BLog:
<https://blog.min.io/hdd-durability-erasure-coding/>
- Average failure time: 2y8m for HDD
- Bit rot on large disks
- Block-level RAID v.s. object storage erasure coding
- Rebuilding time / backup time

Read about iSCSI

- SCSI == Small Computer System Interface
- What does the following terms mean?
 - iSCSI target
 - iSCSI initiator
 - iSCSI LUN
- Benefit over NFS or SMB?
(Note: iSCSI is not a network file system)

State

- State:
e.g., files that each client has open.
- State**less**: if the server does not track the status of the users & files
- Stateful: otherwise.
- Stateful is more complex, but allow more control over files and their management.

Stateful v.s. stateless

	Stateful	Stateless
Pros	Smaller requests	Easy server crash recovery
	Simpler request processing	No open/close needed
	Better cache coherence, file locking, etc.	Better scalability
Cons	Per-client state limits scalability	Each request must be fully self-describing
	Fault-tolerance on state required for correctness	Consistency is harder, e.g., no simple file locking

Performance Concerns

- Goal:
transparent == no difference from local access
- Challenge: network latency (especially over WAN)
- Techniques:
 - Read-ahead caching:
preload the file into local memory
 - Batch writes (write behind as opposed to write through)
cache writes in memory and send them in batches

NFS history

- NFS v2:
client write op. is completed until ack from the server (read: HIGH DELAY!), UDP only
- NFS v3:
asynchronous writes, TCP or UDP
(NFS v2 should not be used now)
- NFS v4: numerous enhancements, TCP only! (congestion control)
Compatibility with firewall & NAT devices
Lock & mount —> core NFS protocol
ACLs
Unicode filenames
Good performance on low-bandwidth connections
- NFS FAQ: <http://nfs.sourceforge.net>
Read A1, A4, A6. Google for the terms you don't understand and try to learn these.

Security

- Bottom line: allow files to be accessed (read/write) **from the network** (read: entire world)!
- Access control
- How to authenticate the users?
- Modern solution: centralized authentication system

NFS Security

- Flavors of authentication:
 1. AUTH_NONE: no authentication
 2. AUTH_SYS: UNIX-style user & group access control
 3. RPCSEC_GSS: a powerful flavor that ensures integrity and privacy plus authentication

NFS Security

- AUTH_SYS: how to attack?
 - Take control of a client machine that is allowed to access the NFS
 - **Pretend** that a user that owns the file is authenticated, and tell NFS server to serve the file to the client machine

Root access

- In NFS-mounted filesystems, usually root is changed to run as nobody (or other similar account)
- Prevent files owned by root to be accessed by the world
- But cannot protect user files (since root of the client can su to become other user)

Server configuration

- /etc/exports: specify the directories to share
- Each line: <path(local)> <client>(options)
Example:
/mnt/backup 140.112.31.40(rw,async)
- See manpage exports(5) (man 5 exports)
- Possible client ID: IP (192.168.1.1), IP networks (192.168.1.0/24), hostnames (www.csie.ntu.edu.tw), wildcards (*.csie.ntu.edu.tw) — hostname determined via reverse DNS lookup
- Common options: ro/rw, sync/async, root_squash/no_root_squash/all_squash
- Package: nfs-kernel-server

Client configuration

- Example:
mount nfs.csie.ntu.edu.tw:/mnt/backup /mnt/
backup_nfs_csie
- Put it in /etc/fstab for mounting at start-up
- What's the downside of putting it in fstab?
- Package: nfs-common

Why Automount

- Downsides of putting NFS filesystems in fstab:
 1. Maintaining fstab file on 100+ machines is tedious (different needs on different machines)
 2. Dependency on multiple servers (hung commands)
 3. No backup provisions

Automount

- Mounts a virtual filesystem at locations for automatic mounting
- Mount the filesystems “on-demand”
- Unmount when a filesystem is not used for a time duration (time-out)
- Check out packages: autofs, autofs5
